Kepada yth Dewan Editor
Buletin Peternakan Fapet UGM

Terima kasih saya ucapkan atas saran dan masukan untuk naskah saya yang berjudul "Determination of Morphological Characteristic in Kuantan Cattle Using Multivariate Analysis". Berikut ini saya lampirkan naskah yang sudah saya perbaiki sesuai masukan dan saran dari reviewer dan editor (Perubahan dalam teks, saya tandai dengan warna kuning). Demikian saya sampaikan, atas perhatian Bapak dan Ibu, saya ucapkan banyak Terima Kasih.

Wassalam

# Determination of Morphological Characteristic in Kuantan Cattle Using Multivariate Analysis

## ABSTRACT

The objective of this research was to characterized morphology and estimated genetic distance between the population of Kuantan cattle. A Total of 213 cattle (44 male and 169 female with age ranging from 2-3 years) were used in this study and collected from extensive ranging systems in three sub-population (Cerenti, Inuman, and Kuantan Hilir regions) Kuantan Singingi Regency, Riau Province. Five variables were measured that is Body Length (BL)(cm), Wither Height (WH)(cm), Hip Height (HH)(cm), Chest Girth (CG)(cm), and Chest Depth (CD)(cm). Data obtained were analyzed, descriptive analysis, Principal Components Analysis (PCA) and Hierarchichal Clustering Analysis (HCA) using XLSTAT program. All variables of body measurement in the Kuantan Hilir region were higher than Cerenti dan Inuman, Kuantan Singingi Regency, Riau Province. The first factor in PCA described body measurement contributed 32.77%, and the second factor described body shape contribute 25.83% of total variability. The dendrogram showed there is three clusters of Kuantan Cattle.

**Keywords:** Kuantan cattle, PCA, Genetic Distance, Morphological Characteristics

## Introduction

Indonesia has a large variety of indigenous animal genetic resources (AnGR). One of them is Kuantan cattle. Kuantan cattle are one of the local breeds in Riau Province (Indonesia) that play an important role in the maintenance of rural population living, social, religious, and traditional celebration. Kuantan cattle in Riau Province very adaptive in an extensive management system, and lack quality feeder. Based on data in the Kuantan Singingi government, the population of Kuantan cattle decreasing from 2016/2017.

**Commented [A1]:** Tampilkan data populasi dan penurunannya sejak 2016/2017 hingga sekarang.

90The decrease in grazing areas and lack of bulls make the population decrease. The absence of a structured and targeted breeding program in Kuantan cattle, and the crossing of Kuantan cattle with other breeds without evaluation, is feared genetic drift. FAO (201P5) states that cattle are categorized into endangered groups if the total number of males is less than or equal to 20 and greater than 5.

Conservation and production program require strategy in management and detail information about animal genetic resources (FAO, 2013). Morphological characterization of the breed, very important to develop the breeding scheme. Improvement in the breeding system is very important to increase the population and to improve the quality of Kuantan cattle.

The multivariate technique is one of the methods to characterize local breed and has been found very suitable to identified genetic variation within and between populations. PCA can identify the major quantitative variable, and discriminant analyses more suitable in assessing to evaluate their differentiation. Recently, this technique has been suitable to characterize Indonesia local breed cattle (Bali cattle (Hikmawaty *et al*. 2017), Pasundan Cattle (Sulasmi *et al.,* 2017)), Ongol and Sumba Ongol (Putra *et al*., 2020) Aceh Cattle (Mahmudi *et al*., 2019), Katingan Cattle (Utomo, 2010), Pesisir Cattle (Adrial, 2010), Indonesia local sheep (DEG Madura and Rote) (Gunawan and Sumantri, 2007), Ethiopia local sheep (Wagari *et al*., 2020), Nigeria local sheep (Dauda *et al*., 2018), Indonesian local buffalo (Anggraeni *et al*., 2011; Rusdin *et al.*, 2018; Johari *et al.,* 2009). Based on those research, it is very important to conduct a study on morphological characteristic at kuantan cattle in different population There has not been any report related to this matter before. The present study aimed to describe the morphological characteristic and estimated genetic distance between the population of Kuantan cattle from three subpopulations (Cerenti, Inuman, and Kuantan Hilir).

## Materials and Methods

This study was conducted in Kuantan Singingi Regency. It is located at 0º00' North Latitude - 1º00' South Latitude and 101º02' East Longitude - 101º55' East Longitude (Figure 1).

### Data Collection

Quantitative morphological traits were observed in 40 Kuantan male, and 150 Kuantan females. Location and number of the animal were determined by purposive sampling. Three regions were selected, that is Cerenti, Kuantan Hilir, and Inuman. only animal within the age range 2 to 3 years were considered. Five body measurement taken were 1) Body Length (BL)(cm):Distance with the shoulder Joint (tuberculous humeri) to the pelvic bone (tuber ischia), 2) Hip Height (HH) (cm): Vertical distance from peak hip to the standing ground, 3) Wither Height (WH)(cm): wither peak, trough scapula to the standing ground, 4) Chest Girth (CG) (cm): Body circumfencem behind the forelegs, 5) Chest Depth (CD)(cm) (Figure 2). The age of animal was estimated by the dentition method.

### Statistical Analysis

Descriptive statistics (mean, SE, and CV) and t test were used to analyzed body measurement. PCA was used to determine the major quantitative variable and the person's coefficient correlation (r) between them and analyzed using XLSTAT (Vidal *et al.,* 2020). The Dendogram was created based on Hierachical Clustering Analysis (HCA) using XLSTAT program.

## Results and Discussions

### Descriptive and Principle Component Analysis (PCA) of Kuantan cattle

The population of Kuantan cattle found in two regions, Kuantan Singingi and Indragiri Hulu. Cerenti, Kuantan Hilir, and Inuman located in Kuantan singingi. This region is adjoining West Sumatera Province. Generally, Kuantan cattle have a small size like pesisir cattle in West Sumatra. These cattle were reared mainly on an extensive rearing system (Figure 3). The coat color of Kuantan cattle varied in different colors i.e. white, brown, grey, and black.

Descriptive statistics (Mean and Covariant Variance (CV) of Kuantan cattle were shown in Table 1. Chest Girth trait of Kuantan Cattle in Kuantan Hilir subpopulation, differ significantly higher than Cerenti and Inuman. Genetic and Environment has been the main factor in influenced of body measurement. This result corresponds well with Pundir *et al.,* (2015) who also find a difference significantly in body measurement between the population in three Indigenous cattle in India. Sex factors also affected body measurement. Jakaria *et al.,* (2019) reported live body weight and body measurement of Bali cattle for males are higher than females. Said *et al.,* (2017) also reported morphometric traits on Pasundan cattle males were higher than females. The minimum variability of Kuantan cattle male and female trait in wither height, and maximum variability in chest depth.

Variation of body measurement could indicate screening adaptive genetic diversity. The body measurement of kuantan cattle was observed in this study lower than some adult Indonesian indigenous and local cattle such as Bali, pasundan, pesisir, Katingan, and Madura cattle (Said *et al*., 2017; Adrial., 2010). All variable also lower than Indigenous cattle in other countries, such as kuri cattle from Nigeria (Grema *et al.,* 2017), Begait cattle from Ethiopia (Makonnen *et al*., 2020), Sudan Zebu Cattle from Sudan

(Alsiddig *et al.,* 2020), and indigenous cattle of assam from India (Keyastha *et al.,* 2020).

Pearson's correlation coefficient between all variables according to Principal Component Analysis (PCA) were shown in Table 2. Some values are found to be higher than 0.3 and indicated a significant correlation. A significant correlation between, BL-WH, WH-CG, HH-CG, and CG-CD. A highly positive correlation was found between CG-CD.

This correlation corresponds well with Putra *et al.,* (2020) who also find a positive correlation between CG and CD in Pasundan Cow (0.56). this estimate was higher compare to Adinata *et al*., (2016), who reported CG and CD correlation in Jabres cattle 0.247. Tyasi *et al*., (2020) also determined the correlation between body measurement and the bodyweight of Nguni cattle, and conclude there is a highly positive correlation. However, score correlation between body measurement influenced by breed, age, and type of animal.

Eigenvalues and percent of total variance along with factor loading body measurement of Kuantan cattle are shown in Table 3. Three factors with eigenvalues superior to 1 were observed. The first factor explained 32.77% variance effect by body measurement (positively high for CG, WH, and CD). The second factor described body shape contributes 25.83% of the total variability. Another study on local cattle in Indonesia, such as Sulasmi *et al*., (2017), showed body length and chest circumference as an identifier body size and shape of Pasundan Bull, but in pasundan cows, the identifier of body size and shapes of pasundan cows were body length and high at withers. The proportion of total variance explained by the first component in this study lower than Pasundan Cattle Sulasmi *et al*., (2017); Putra *et al*., (2020), Aceh cattle, PO,

and Bali (Mahmudi *et al*., 2019), Taro white Cattle (Heryani *et al.,* 2018), but higher than assam hill cattle (21.93%),

Animal's plot in bi-dimensional representation (F1-F2) according to PCA shown in Figure 4. The bi-dimensional presentation of individuals showed that the Kuantan cattle were not separated based on three populations.

**Identification of Kuantan Cattle Group using Hierarchical Cluster Analysis (HCA)**

The dendrogram showed that there are three clusters of Kuantan cattle based on HCA in six (6) quantititative morphological trait (Figure 5). First cluster consists of 66 animals, mostly from Inuman sub population. Second cluster include of 79 animals, mostly from Kuantan Hilir sub population, and third cluster, include of 46 animals, mostly from Cerenti. Based on dendogram, Kuantan cattle in Kuantan hilir sub population have a significant distanced with Cerenti sub population.

Bacchouce *et al.,* (2015) also found three cluster based on HCA analysis of native bovine population in Northen Tunisia, and each cluster consist of animal from different populations. Eduoard *et al.,* (2019) also classified west african dwarf ewes to three clusters based on eight major quantitative morphological variable. Each cluster were unspecific with the three agro ecological zones of the study.

**Conclusion**

All the traits in Body Measurement were higher in Kuantan Hilir than that of Cerenti and Inuman. PCA analysis showed the first factor explained 32.71% variance effect by body measurement (Positively high for CG, WH, and CD). The second factor described body shape contributes 25.87% of the total variability. The dendrogram showed there are three clusters of Kuantan Cattle based on HCA Analysis.

**Commented [A2]:** Hasil dendogram ini mohon dikaji/dimaknai lebih dalam. Perlu di jelaskan secara ilmiah alasan atau dugaan bahwa mengapa bisa terjadi jarak genetik yang cukup jauh antara sapi Kuantan di sub populasi Kuantan Hilir dengan di sub populasi Cerenti ? Apakah karena akibat pengaruh geografis, atau adanya penyisipan gen asing pada salah satu sub populasi, atau pengaruh lainnya (misal adanya kebijakan pemerintah). Perlu juga dijelaskan upaya konservasi apa yang perlu dilakukan agar ke depan populasi sapi Kuantan di ketiga sub populasi tersebut tidak jauh jarak genetiknya ? Atau bagaimana upaya meningkatkan produktivitas sapi Kuantan berdasarkan informasi perbedaan jarak genetik tersebut ? Intinya, perlu kajian lebih dalam dalam memaknai hasil dendogram.

## Introduction

Indonesia has a large variety of indigenous animal genetic resources (AnGR). One of them is Kuantan cattle. Kuantan cattle are one of the local breeds in Riau Province (Indonesia) that play an important role in the maintenance of rural population living, social, religious, and traditional celebration. Kuantan cattle ~~in Riau Province~~ very adaptive in an extensive management system, and lack quality feeder. Based on data in the Kuantan Singingi government, the population of Kuantan cattle decreasing from 2016/2017.

**Commented [A1]:** Any reason about that?? Presently, How many population of Kuantan cattle? Put in this part

~~90~~The decrease in grazing areas and lack of bulls make the population decrease. The absence of a structured and targeted breeding program in Kuantan cattle, and the crossing of Kuantan cattle with other breeds without evaluation, is feared genetic drift. FAO (201P5) reported ~~states~~ that cattle are categorized into endangered groups if the total number of males is less than or equal to 20 and greater than 5.

Conservation and production program require strategy in management and detail information about animal genetic resources (FAO, 2013). Morphological characterization of the breed, very important to develop the breeding scheme. Improvement in the breeding system is very important to increase the population and to improve the quality of Kuantan cattle.

The multivariate technique is one of the methods to characterize local breed and has been found very suitable to identified genetic variation within and between populations. ..... (PCA) can identify the major quantitative variable, and discriminant analyses more suitable in assessing to evaluate their differentiation. Recently, this technique has been suitable to characterize Indonesia local breed cattle (Bali cattle (Hikmawaty *et al*. 2017), Pasundan Cattle (Sulasmi *et al.,* 2017)), Ongol and Sumba Ongol (Putra *et al*., 2020) Aceh Cattle (Mahmudi *et al*., 2019), Katingan Cattle (Utomo, 2010), Pesisir Cattle (Adrial, 2010), Indonesia local sheep (DEG Madura and Rote) (Gunawan and Sumantri, 2007), Ethiopia local sheep (Wagari *et al*., 2020), Nigeria local sheep (Dauda *et al*., 2018), Indonesian local buffalo (Anggraeni *et al*., 2011; Rusdin *et al.*, 2018; Johari *et al.,* 2009). Based on those research, it is very important to conduct a study on morphological characteristic at kuantan cattle in different population. There has not been any report related to this matter before. The present study aimed to describe the morphological characteristic and estimated genetic

distance between the population of Kuantan cattle from Tthree sub_populations (Cerenti, Inuman, and Kuantan Hilir).

## Materials and Methods

This study was conducted in Kuantan Singingi Regency. It is located at 0º00' North Latitude - 1º00' South Latitude and 101º02' East Longitude - 101º55' East Longitude (Figure 1).

### Data Collection

Quantitative morphological traits were observed in 40 Kuantan male, and 150 Kuantan females. Location and number of the animal were determined by purposive sampling. Three regions were selected, that is Cerenti, Kuantan Hilir, and Inuman. only animal within the age range 2 to 3 years were considered. Five body measurement taken were 1) Body Length (BL)(cm):Distance with the shoulder Joint (tuberculous humeri) to the pelvic bone (tuber ischia), 2) Hip Height (HH) (cm): Vertical distance from peak hip to the standing ground, 3) Wither Height (WH)(cm): wither peak, trough scapula to the standing ground, 4) Chest Girth (CG) (cm): Body circumfencem behind the forelegs, 5) Chest Depth (CD)(cm) (Figure 2). The age of animal was estimated by the dentition method.

### Statistical Analysis

Descriptive statistics (mean, SE, and CV) and t test were used to analyzed body measurement. PCA was used to determine the major quantitative variable and the person's coefficient correlation (r) between them and analyzed using XLSTAT (Vidal *et al.,* 2020). The Dendogram was created based on Hierachical Clustering Analysis (HCA) using XLSTAT program.

## Results and Discussions

**Formatted:** Indonesian

### Descriptive and Principle Component Analysis (PCA) of Kuantan cattle

The population of Kuantan cattle found in Ttwo regions, Kuantan Singingi and Indragiri Hulu. ~~Cerenti~~, Kuantan Hilir, and Inuman located in Kuantan singingi. This region is adjoining West Sumatera Province. Generally, Kuantan cattle have a small size like pesisir cattle in West Sumatra. These cattle were reared mainly on an extensive rearing system (Figure 3). The coat color of Kuantan cattle varied in different colors i.e. white, brown, grey, and black.

**Commented [A2]:** What do you mean????you mean is curently??

Descriptive statistics (Mean and Covariant Variance (CV) of Kuantan cattle were shown in Table 1. Chest Girth trait of Kuantan Cattle in Kuantan Hilir subpopulation, differ significantly higher than Cerenti and Inuman. Genetic and Environment has been the main factor in influenced of body measurement. This result corresponds well with Pundir *et al.,* (2015) who also find a difference significantly in body measurement between the population in three Indigenous cattle in India. Sex factors also affected body measurement. Jakaria *et al.,* (2019) reported that live body weight and body measurement of Bali cattle for males are higher than females. Said *et al.,* (2017) also reported that morphometric traits on Pasundan cattle males were higher than females. The minimum variability of Kuantan cattle male and female trait in wither height, and maximum variability in chest depth.

Variation of body measurement could indicate screening adaptive genetic diversity. The body measurement of kuantan cattle was observed in this study lower than some adult Indonesian indigenous and local cattle such as Bali, pasundan, pesisir, Katingan, and Madura cattle (Said *et al*., 2017; Adrial., 2010). All variable also

lower than Indigenous cattle in other countries, such as kuri cattle from Nigeria (Grema *et al.,* 2017), Begait cattle from Ethiopia (Makonnen *et al*., 2020), Sudan Zebu Cattle from Sudan (Alsiddig *et al.,* 2020), and indigenous cattle of assam from India (Keyastha *et al.,* 2020).

Pearson's correlation coefficient between all variables according to Principal Component Analysis (PCA) were shown in Table 2. Some values are found to be higher than 0.3 and indicated a significant correlation. A significant correlation between, BL-WH, WH-CG, HH-CG, and CG-CD. A highly positive correlation was found between CG-CD.

This correlation corresponds well with Putra *et al.,* (2020) who also find a positive correlation between CG and CD in Pasundan Cow (0.56). this estimate was higher compare to Adinata *et al*., (2016), who reported CG and CD correlation in Jabres cattle 0.247. Tyasi *et al*., (2020) also determined the correlation between body measurement and the bodyweight of Nguni cattle, and conclude there is a highly positive correlation. However, score correlation between body measurement influenced by breed, age, and type of animal.

Eigenvalues and percent of total variance along with factor loading body measurement of Kuantan cattle are shown in Table 3. Three factors with eigenvalues superior to 1 were observed. The first factor explained 32.77% variance effect by body measurement (positively high for CG, WH, and CD). The second factor described body shape contributes 25.83% of the total variability. Another study on local cattle in Indonesia, such as Sulasmi *et al*., (2017), showed body length and chest circumference as an identifier body size and shape of Pasundan Bull, but in pasundan cows, the identifier of body size and shapes of pasundan cows were body length and high at withers. The proportion of total variance explained by the first component in this

study lower than Pasundan Cattle Sulasmi *et al*., (2017); Putra *et al*., (2020), Aceh cattle, PO, and Bali (Mahmudi *et al*., 2019), Taro white Cattle (Heryani *et al.,* 2018), but higher than assam hill cattle (21.93%),

Animal's plot in bi-dimensional representation (F1-F2) according to PCA shown in Figure 4. The bi-dimensional presentation of individuals showed that the Kuantan cattle were not separated based on three populations.

**Identification of Kuantan Cattle Group using Hierarchical Cluster Analysis (HCA)**

The dendrogram showed that there are three clusters of Kuantan cattle based on HCA in six (6) quantititative morphological trait (Figure 5). First cluster consists of 66 animals, mostly from Inuman sub population. Second cluster include of 79 animals, mostly from Kuantan Hilir sub population, and third cluster, include of 46 animals, mostly from Cerenti. Based on dendogram, Kuantan cattle in Kuantan hilir sub population have a significant distanced with Cerenti sub population.

Bacchouce *et al.,* (2015) also found three cluster based on HCA analysis of native bovine population in Northen Tunisia, and each cluster consist of animal from different populations. Eduoard *et al.,* (2019) also classified west african dwarf ewes to three clusters based on eight major quantitative morphological variable. Each cluster were unspecific with the three agro ecological zones of the study.

## Conclusion

All the traits in Body Measurement were higher in Kuantan Hilir than that of Cerenti and Inuman. .....(PCA) analysis showed the first factor explained 32.71% variance effect by body measurement (Positively high for CG, WH, and CD). The second factor described body shape contributes 25.87% of the total variability. The

dendrogram showed there are three clusters of Kuantan Cattle based on HCA Analysis.
