a. Pengutipan hanya untuk kepentingan pendidikan, penelitian, karya Abstract -Electrical energy has become a basic need that Eannot be eliminated in everyday life for Indonesian \vec{p} eople, where the source of electrical energy is currently will fossil fuels. One way to overcome excessive exploitation of fossil fuels is to utilize renewable energy sources, namely wind energy. Wind has a great potential penulisan for generating electrical energy with the conversion that Eccurs in the Permanent Magnet Synchronous Generator PMSG). PMSG is one of the components in a wind power plant (PLTB). Current wind conditions in Indonesia cause karya Tow efficiency in PMSG, where many things affect this, one of which is power losses in the generator, copper losses caused by the copper winding on the stator getting hot, and ilmiah, penyusunan iron losses because the generator has bearings. get hot. Many factors can cause efficiency to increase, such as the Fore speed and core thickness used in PMSG. In this paper, image of the 24 slot, 16 pole PMSG model will be Freated with variations in rotational speed and core thickness using the MagNet Infolytica software by Simulating the software using the Finite Element Method FEM). Variations of speed used are 250 rpm, 500 rpm, laporan, penulisan kritik atau and 750 rpm, with variations in core thickness of 40 mm, 60 mm, and 80 mm. The simulation results that occur in variations in current, voltage, torque, input power, and input power all increase according to Faraday's law. The highest efficiency value was obtained at 82.20% at a core thickness of 40 mm and a rotating speed of 500 rpm, with a current value of 9,926 Amperes, a voltage of 99,263 Volts, a torque of 22,904 Nm, an input power of 1198.64 Watts, and an output power of 985.28 Watts.

I. INTRODUCTION

Electrical energy has become a basic need that cannot **be** eliminated from everyday life for Indonesians. The need for electrical energy directly increases every year along with the growth of the existing population [1]. The source of electrical energy comes from two sources: renewable energy and non-

Sultan Syarif Kasim State Islamic University Riau, HR. Soebrantas Street Num. 155 Simpang Baru, Panam, Pekanbaru, 28293 liliana@uin-suska.ac.id

renewable energy sources. Currently, the average source of electrical energy uses non-renewable energy sources. Non-renewable energy is energy that takes a long time to form, has very limited availability, and is also damaging to the environment. If energy is nonrenewable and is exploited continuously, it will run out and take a long time to be utilized again. [2].

There are various examples of non-renewable energy, one of which is coal. Coal is in the second rank, which dominates its use in Indonesia. This is because most of the existing power generation sectors use coal as fuel in power plants to produce electricity [1]. While the use of coal fuel has a direct impact on the environment, the resulting carbon dioxide emissions damage the surrounding environment. Power plants that use coal as fuel can produce radioactive substances that can damage human health 100 times more than nuclear power plants [3].

While there are still energy sources that can be used to generate electricity, for example, renewable energy sources, Renewable energy sources are energy sources that come from nature and can be used freely. These renewable energy sources can also be renewed indefinitely. To help meet Indonesia's increasing demand for electrical energy, renewable energy sources can be utilized to the fullest. Indonesia has not yet made full use of renewable energy sources. Examples of renewable energy sources are solar, water, geothermal, wind, and so on. [3].

Wind energy is an alternative energy source that has good prospects because it is always available in nature and is a clean and renewable energy source [4]. Wind energy has great potential in Indonesia, but it has not been fully utilized as a source of electrical energy. There are several things that affect the existence of wind energy, such as weather, ambient temperature, altitude above sea level, and so on. Wind energy is also fluctuating because conditions are always changing. By utilizing wind energy, it will solve the problem of using non-renewable energy such as coal, oil, and so on [5][6].

J

To convert wind energy into electrical energy, a generatorocalled Pembangkit Listrik Tenaga Bayu e B **PETB**) is needed. In the conversion process using a Book called a generator. The types of generators that gane be used are: Permanent Magnet Synchronous Pengutipan hanya Generator 24 Slot 16 Pole (PMSG) capable of Broducing magnets quickly. The problem that occurs m Endonesia itself is that the potential for wind energy the low, can sing the efficiency that occurs in PMSG to alse be low. In PMSG, wind speed affects the output a untuk Ralues of torque, current, and voltage, where increasing or adding rotational speed causes the kepentingan gurgent and voltage to increase quickly. The resulting magnet will be bigger according to Faraday's law. Not Buly the totational speed, which can be used as a Senchmark for increasing the value of torque, current, and voltage, but there are still many variables that can pendidikan, be changed to increase the efficiency value of PMSG, one of which is the thickness of the iron core in PMSG. The thickness of the iron core in PMSG can also be a factor in increasing the values of torque, current, and penelitian, penulisan xoltage, which is also related to Faraday's law: the thicker the iron core, the better the output value that Securs in PMSG [2], [5].

Permanent magnet Synchronous Generator 24 solot 16 Pole is a generator that has a permanent magnet that has a slot or coil on the generator as much as 24 s of space for coils, and also 16 pole here is the number karya If magnets in pairs with 8 magnets pointing south and a magnets also pointing south. Generators are also ilmiah, penyusunan Fools that help convert mechanical energy into electrical energy using electromagnetic induction generated from the permanent magnets in the generator [5]. At PMSG 24 slots, 16 poles own gogging pess the low. Cogging less means we can generate electricity at low wind speeds. Cogging less in PMSG 24 slot 16 pole has a torsional deflection \vec{v} aused by the interaction of a permanent magnet with the ability of a material to transmit magnetic flux. Cogging Tess low can cause low sound and vibration [2], [5].

laporan, penulisan kritik atau PMSG efficiency is obtained by comparing the output (*Pout*), which will be compared with the input power (Pin) on generators. There are many things that can affect the efficiency of the generator, such as the material fised in designing the generator, the load or power used, and the low speed, which causes the tinjauan turbine to not move. In addition to the factors that increase efficiency, there are also those that can reduce the efficiency of the generator, such as power losses in suatu masalah the generator, which can reduce efficiency; copper losses caused by the copper windings on the (Pin) stator getting hot; and iron losses due to the generator's bearings getting hot. The way to get efficiency is to compare the power output with the power input, which is the input power (Pin), which is obtained from the results of **t**orque data or the rotation of the rotor, which rotates according to a predetermined speed and angle. As for the output power (Pout), it is obtained from the current and voltage generated due to changes in

mechanical energy that rotate in the generator between the stator and the rotor. The higher the efficiency, the better the quality produced by the generator [5].

Performance from the *Permanent Magnet Synchronous Generator* depends on the magnitude of the magnet generated from magnetic induction with the rotor, where the magnet located at the end of the rotor induces a voltage in the winding that is on the stator. Therefore, the thickness of the core and the rotational speed of the permanent magnet synchronous generator (24 slots, 16 poles) The more it is increased, the better the current and voltage will be, thus affecting the characteristic values, namely current, voltage, power input, one output, and efficiency, on a permanent magnet synchronous generator with 24 slots and 16 poles [7].

Research related to PMSG to increase efficiency has been done. In the discussion raised regarding the effect of the number of turns and rotational speed on synchronous efficiency in permanent magnet generators (18 slots, 16 poles) in 2022, research is being carried out regarding the addition of windings and rotational speed to increase the efficiency that occurs in PMSG using the Finite Element Method (FEM), where the speeds used are 500 rpm, 1000 rpm, and 1500 rpm with variations of 50, 75, and 100 turns, and the load used is 10 ohms for each variation used. The results of the research carried out with the highest efficiency were found in 75 coils with a speed of 1500 rpm; the efficiency value was 80.9% [5] [8]. Subsequent research was carried out by varying the thickness of the iron core to the output power of 1 kW; the thickness variations used were 37mm, 52 mm, and 80mm. The thickness of the iron core of the rotor and stator can affect the output value depending on the characteristics of the generator. The effect of the iron core on the output power arises due to the formation of a magnetic field and magnetization ability. This magnetic field will increase the electric field generated from a piece of wire that is in a changing magnetic field. The results of the study show the largest values of current, voltage, and torque produced at 80 mm thick, with values of 17.44 A, 52.31 V, and 24.84 Nm. Incoming power produces a large comparison; it is proven that at a thickness of 52 mm, it produces 766 watts, while at a thickness of 80 mm, it can produce 1300 watts. The highest output power is 1 kW with a thickness of 80 mm [2].

The magnetic material also influences the characteristics of the PMSG. As research has been carried out in 2022, many magnetic materials can also be used, where the magnetic material has different properties. Permeability is directly proportional to the speed of the magnetic flux, and the better the material used in the magnet, the better the permeability produced. The permeability value for each material is different. As shown, there are research results where the highest output power and efficiency are produced by PM12 material: Br 1.2 nut 10, where the output

N

0

power value is 1312.19 watts with an efficiency of 91% [8].

In 2021, has anyone researched the effect of the e B Pengutipan hanya untuk Hugsber of turns on the PMSG? Where the number of Eurry in the stator coil is increased, the resulting output alse increases. In the study, the number of coils used Byas 10, 50, and 75. Where each winding produces a different value, and the value of the electric power of The big propeller is obtained in coil 75 with a value of 2562 Watts [9].

5 In making and designing the generator in this Study using the software-based Finite Element Method kepentingan **GFEMS**), **FEM** is a method used to solve problems as differential and integral by calculating the garameters one by one for each part of the object to be Enalysed In the smallest part. In carrying out FEM, There are several processes, namely discretizing, which pendidikan, divides into several parts or several elements; creating an estimation function to see the potential of the elements; estimating the matrix value of the elements; Estimating the value in the system; and getting a penelitian, calculated system solution. Finity element method FEM) is in software at MagNet Infolityca, which is used to carry out generator designs by varying the Broblems, and getting the generator design as desired [10]. penulisan

In the research that will be carried out using the karya material Remko pure iron for stator and rotor, materials Remko: soft pure iron has a high permeability; on *coil*, using materials Cooper: ilmiah, **5**.77.c7siemens/meter; and on magnet, using PM12 material: Br 1.2, Nut 1.6, with a total of 65 turns and a penyusunan laporan, penulisan kritik atau tinjauan suatu masalah Bead of 10 ohm, and the same for each variation. For variations in core thickness ranging from 40 mm, 60 mm, and 80 mm with variations in rotational speed of **2**50 rpm, **5**00 rpm, and 750 rpm. nber:

II. METHODS

1. **Research Flow Chart**

In the research that will be carried out this time using the experimental method by modeling the PMSG 24 slot 16 pole and simulating PMSG, followed by calculating the data from the simulation results to get the optimal efficiency value, Figure 1 shows the research flowchart to be carried out.

tan Syarif Kasim Riau

Figure 1. Research Flow Chart

The Flow chart above states the flow of research carried out, which begins with a study of literature sourced from journals that have been published, followed by collecting the required data. Starting from the specific data for modeling the generator to the component data on the generator such as the stator, rotor, magnet, and airbox. Data on core thickness and rotational speed are also needed in order to be able to run simulations in research. After getting the required data, proceed with modeling a permanent magnet synchronous generator on the software MagNet Infolityca. The next process will be modeling PMSG 24 slot 16 pole, starting with designing the stator, rotor, airbox, and permanent magnets, then entering the variables used in this study, which use iron core thicknesses of 40 mm, 60 mm, and 80 mm, and variable rotational speeds starting from 250 rpm, 500 rpm, and 750 rpm. The next step is to enter the load value and the number of windings used, where the load value and the number of coils can be said to be the same variable for each core thickness, as well as the rotational speed in this study. The load value used is 10 ohms, and the number of turns is 65. The material used for modeling PMSG 24 slot 16 pole is Remko Pure Iron: Soft Pure Iron, on the magnetic part, PM12: Br 1.2 Mur 1.6, for the air gap and airbox, Air.

2. Data Collection

In conducting research, the initial step is to collect the required data from related journals or generator

Pengutipan hanya untuk kepentingan pendidikan, penelitian, penulisan karya ilmiah, penyusunan laporan, penulisan kritik atau tinjauan Motive Force (EMF), such as increasing the magnetic Held, expanding the area, and increasing the number of coils turns. The magnetic flux itself is the amount or size of the magnetic field that will pass through a certain variable cross-sectional area. According to Faraday, the induction emf in the coil is proportional to the rate of change of the magnetic flux enclosed by the coil, where the faster the change in magnetic flux occurs, the greater the induction emf that arises [2] [12].

PMSG Modeling 24 Slot 16 Pole 3.

MSG 24s16p is a generator that has 24 coils and a total of 26 magnetic poles, where each magnet has 8 leads north and 8 leads south. For modeling done using software From MagNet Infolityca, the total number of turns here is 65, and the load given is 10 ohms. Here are the steps to make a model on PMSG 24 slot 16 pole:

Riau

suatu masalah

The initial modeling stage for PMSG 24s16p is to establish the components in the generator, such as the stator and rotor, to be used. Determine the number of turns to be used on the coil, the magnet to be used, and the material on the air gap and air box. When this step has been fulfilled, proceed with determining the material to be used in the iron core.

Figure 3. Making Components on the Stator and Rotor with Material Remko: Soft Pure Iron.

At this stage, modeling the PMSG 24 generator components slot 16 poles that will be used. The stator and rotor use the 24s16p material Remko: Soft Pure Iron, where this material has the advantage of having a high permeability value. The permeability value that exists in the material Remko Soft Pure Iron is 0,00004 Wb/Am [13] [14].

4. Determination of Core Thickness dan Spin Speed

e B

Pengutipan hanya untuk

kepentingan

So, the next step is to determine the thickness of the rotational speed. The thicker the core used in PMSG, the better the output. The rotational append is an accordance with Faraday's law, which states that the higher the speed, the better the output wilk be in PMSG. The rotating speeds used in PMSG histime are 250 rpm, 500 rpm, and 750 rpm [2] [5].

5. Determination of Number Coils and Loading

a1. Determination of the number of coils SAfter entering the various materials required in tator and rotor, determine the number of coils to be ased. The number of turns on the stator affects the and ced voltage produced, so if the number of turns on the stator coil increases, the greater the induced $\overline{\Xi}$ oltage that will be generated by the generator [11]. The number of turns used in this study is 65 on each igoil.

Coil in PMSG 24 Slot 16 Pole a

Loading 2.

R

After determining the number of coils to be used proceed with describing the circuit phase diagram for each coil that will be loaded. To get the results, the generator must be loaded, which in this study uses a loading of 10 ohms. Loading and circuitry are shown below .:

Gambar 5. Network Circuit and Imposition of PMSG 24 Slot 16 Pole

6. PMSG Modeling Simulation 24 Slot 16 Pole

After doing the modeling on PMSG, the next step is to carry out a simulation and collect data from the simulation results. Data from the simulation results obtained consist of current, voltage, torque, input power, output power, and

efficiency. The data obtained will be transferred to Microsoft Excel, and manual processing will be carried out, followed by a comparative analysis of the efficiency that occurs due to differences in core thickness and rotational speed in the PMSG 24 generator slot and 16 pole. The following data will be issued when running the simulation:

Current 1

The current is obtained from the comparison of the input voltage and resistance. The rotational speed of the generator affects the current value. The greater the rotational speed of the generator, the greater the resulting current value will be [7].

$$I = \frac{V}{R} \tag{1}$$

I = current (Amperes) V = voltage (volt)

R = load (Ohm)

Voltage 2.

The voltage is the result of the generator's electromagnetic induction.

$$\varepsilon = -N\frac{\Delta\phi}{\Delta t} \tag{2}$$

 \mathcal{E} = the induction GGL (V)

N = the number of windings

 $\Delta \emptyset$ = the change in magnetic flux (Wb)

 $\Delta t = time lapse (s)$

3. Torque

Torque is generated from the tangential force and the radius where the motor is working, depending on the magnitude of the applied force and the distance between the rotational and rotary axes [7].

$$T = Fr \tag{3}$$

F = Force

 $\mathbf{R} = \mathbf{Radius}$

Input Power 4.

The equation used to obtain the input power (Pin) are as follows: .

(4)

$$Pin = \frac{\tau x RPM x 2 Phi}{60}$$

Pin = the inlet power (W)

 $\tau = \text{torque (Nm)}$

- n = the rotating speed (rpm)
- Output Power 5.

And to get the output power value (Pout) using the following equation :

$$Pout = V x I \tag{5}$$

6. Efficiency

The efficiency value is obtained from the comparison of the output power (Pout) with the input power (Pin) multiplied by 100% [7]. With the following equation:

$$n = \frac{P_{out}}{P_{in}} x \ 100\% \tag{6}$$

DISCUSSION

2

e B

penulisan

UIN SUSKA RIAL

At the point of discussion, we will analyze the Esearch results starting from the results of current, Roltage, dorque, input power, output power, and efficiency.

Pengutipan hanya untuk kepentingan pendidikan, penelitian, sutput value increases the rotational speed and increases the thickness of the core, the current value will increase. This is because the electromagnetic induction that occurs is increasing in accordance with karya ilmiah, penyusunan laporan, penulisan kritik atau tinjauan suatu masalah Fareday's law regarding electromagnetic induction. The highest current value was obtained at a speed of 350 rpm with a thickness of 80 mm and a current value

Figure 8. Voltage Diagram

The voltage value can also be seen in the average PMSG 24 slot 16 pole output value. The output voltage value is proportional to the current value; when the current value increases, the voltage value also increases because the current and voltage values are comparable. The higher the rotational speed and core thickness of the PMSG, the higher the voltage value.

S

Figure 9. Torque Diagram

The torque value is seen in the average output of PMSG 24 slot 16 pole where the resulting torque value increases because the rotational speed and core thickness are also increased. In the diagram, the thicker the iron core used, the greater the amount of torque generated. The highest torque was produced at a speed of 750 rpm with a thickness of 80 mm and a value of -51.38 Nm.

Figure 10. Input Power Diagram

The input power can be seen from the average output value on the PMSG 24 slot 16 pole; in fact, as the speed and thickness of the core are increased, the input power also increases because the input power is obtained from the multiplication between torque and rotational speed. At each input power and at each variation, the speed and thickness of the core increase because the torque that occurs in the PSMG increases.

5. **Output** Power

The input power can be seen from the average Supput value on the PMSG 24 slot 16 pole; in fact, as the speed and thickness of the core are increased, the to power also increases because the input power is Bbtained from the multiplication between torque and potational speed. At each input power and at each variation, the speed and thickness of the core increase because the torque that occurs in the PSMG increases.

Gambar 12. Efficeincy Diagram

The efficiency value to get the result is the result of dividing the output power (Pout) and input power (Pin) by 100%. The highest efficiency value in this study was at a speed of 500 rpm with a thickness of 40 mm, with a value of 82.20%. Increasing the value of the speed and core thickness given to PMSG does not guarantee an increase in efficiency because PMSG has a limit of how many expansion and widening ratios are included. The decreased efficiency is caused by several factors, including the copper losses caused by the copper windings on the stator becoming hot and the iron Tosses due to the generator having hot bearings.

IV. CONCLUSION

E

After simulating the results of the analysis of core thickness and rotating speed on a 24 slot 16 pole Permanent Magnet Synchronous Generator using software based on the Finite Element Method (FEM), the conclusion of this study is that the thickness of the

core and rotational speed affect the value of efficiency. Because the efficiency value is obtained by dividing the output power by the input power multiplied by 100%, the output power is the result of multiplying the current and voltage. And the input power is the product of torque and rotational speed. The highest efficiency value obtained is 82.20% at a core thickness of 40 mm and a rotational speed of 500 rpm, with a current value of 9,926 amps, a voltage of 99,263 volts, a torque of 22,904 nm, an input power of 1198.64 watts, and an output power of 985.28 watts.
